# Comp151

## Inheritance: Introduction

# Example: University Admin Info

- Let's implement a system for maintaining university administration information.

  - `Teacher` and `Student` are two completely separate classes. Their implementation uses <u>separate</u> code.

  - However, they share many methods and members that are implemented in the same way:  handling name, address, and department.

  - Why do we implement the same function twice?

  - This is not good software reuse!

# Example:  U. Admin Info – student.h

```cpp
enum Department { accounting, business, engineering, mathematics, unknown };
class Student
{
    private:
        string name;
        string address;
        Department dept;
        Course *enrolled;
        int num_courses;
    public:
        Student(string n, string a, Department d) :
            name(n), address(a), dept(d), enrolled(NULL), num_courses(0) { };
        void set_name(const char* name);
        void set_address(const char* adr);
        void set_department(Department dept);
        string get_name() const;
        string get_address() const;
        Department get_department() const;
        bool enroll_course(const string&);
        bool drop_course(const Course&);
};
```

# Example: U. Admin Info – teacher.h

```cpp
enum Rank { instructor, assistant_prof, associate_prof, professor, dean };
class Teacher
{
    private:
        string name;
        string address;
        Department dept;
        Rank rank;
    public:
        Teacher(string n, string a, Department d, Rank r) :
            name(n), address(a), dept(d), rank(r) { };
        void set_name(const char* name);
        void set_address(const char* adr);
        void set_department(Department dept);
        void set_rank(Rank rank);
        string get_name() const;
        string get_address() const;
        Department get_department() const;
        Rank get_rank() const;
};
```

# Things to Consider

- We want a way to say that `Student` and `Teacher` both have the same members: `name`, `address`, `dept`, but yet require them to keep a <u>separate</u> copy of these members.

- We want to <u>share</u> the code for `set_name`, etc., between `Student` and `Teacher` as well.

- We want this code to act like <u>member functions</u> (to permit consistency of <u>state</u> of the objects), so they cannot be written as global functions.

# Solution 1: Re-use by Copying

- Copy the code from one class to the other class, and change the class names.

  - This is very error prone.
  - It is also a maintenance nightmare.
  - What if we find a bug in the code in one class?
  - What if we want to improve the code? Perhaps by introducing a new class `Address`.

- "REUSE by COPYING" is a bad idea!

# Inheritance

- Inheritance enables code reuse.
- Inheritance is the ability to define a new class based on an existing class with a hierarchy.
- The <u>derived class</u> *inherits* the data members and member methods) of the <u>base class</u>.
- New members and methods can be added to the derived class.
- Since the new class only has to implement the behavior that is different from the base class, we can reuse the code for the base class.
- "Inheritance" is the traditional term, but C++ calls it "derivation".

# Solution 2: By Inheritance – person.h

```cpp
class Person
{
    private:
        string name;
        string address;
        Department dept;

    public:
        Person(string n, string a, Department d) :
            name(n), address(a), dept(d) { };
        void set_name(const char* name);
        void set_address(const char* adr);
        void set_department(Department dept);
        string get_name() const;
        string get_address() const;
        Department get_department() const;
};
```

# Solution 2: By Inheritance – student.h

```cpp
class Student : public Person
{
    private:
        Course* enrolled;
        int num_courses;

    public:
        Student(string n, string a, Department d) :
            Person(n, a, d), enrolled(NULL), num_courses(0) { }

        bool enroll_course(const string&);
        bool drop_course(const Course&);
};
```

# Solution 2: By Inheritance – teacher.h

```cpp
class Teacher : public Person
{
    private:
        Rank rank;

    public:
        Teacher(string n, string a, Department d, Rank r) :
            Person(n, a, d), rank(r) { }

        void set_rank(Rank rank);
        Rank get_rank() const;
};
```

# Inheritance

- `Person` is the base class of `Student`.

- `Student` is a derived class of `Person`.

- The effect is that `Student` inherits all data members and methods from `Person`.

- The data members of `Student` are the data members of `Person` ( `name, address, dept` ), plus the extra data members declared in the definition of `Student` ( `enrolled, num_courses` ).

# Example: Inherited Members

```
void some_func(Person& person, Student& student)
{
    cout << person.get_name() << endl;
    cout << student.get_name() << endl;

    student.set_department(engineering);
    Department dept = person.get_department();
    student.enroll_course("COMP151");
    person.enroll_course("COMP001");              // Error!
}
```

# "Is-a" Relationship

- Inheritance implements the <u>is-a</u> relationship.
  - Recall:
    membership (composition) implements the <u>has-a</u> relationship.

- Since `Student` inherits from `Person`,
  - every object of type `Student` can be used like an object of type `Person`
  - all methods of `Person` can be called on a `Student` object

- In other words, a `Student` object definitely <u>is a</u> `Person` object under all circumstances.

- In general:  a derived class object can be treated like a base class object under all circumstances.

# Example: Derived Objects as Base Class Object

```
bool print_mailing_label(const Person& person)
{
    string name = person.get_name();
    string adr = person.get_address();

    // code to print the label
}
```

- Since a `Student` <u>is a</u> `Person`, we can print a mailing label for a student like this:

```
Student student("Tom", "Sai Kung", mathematics);
print_mailing_label(student);
```

# Direct and Indirect Inheritance

- Let's add a new class `PG_Student`:

  **class** PG_Student : **public** Student
  {
      **private**:
          Topic research_topic;
      **public**:
          PG_Student(string n, string a, Department d) :
              Student(n, a, d), research_topic(NONE) { }
          **void** set_topic(**const** Topic& x) { research_topic = x; }
  };

- `PG_Student` is directly derived from `Student`.
- It is <u>indirectly derived</u> from `Person`.
- So a `PG_Student` object <u>is a</u> `Person` object.
- `Person` is called an <u>indirect base class</u> for `PG_Student`.
