Comp151

Generic Programming:
Overloading Operator Functions
From Math Notation to Operators in Programming Languages

• Depending on what programming language you’re using, to program the mathematical equation:
  \[ c = 2(a-3) + 5b \]
  you might have to write things like:
  \[ C = \text{add}(\text{multiply}(2,\text{subtract}(a,3)), \text{multiply}(5,b)) \]

• But most programming languages have operators which allow us to mimic the mathematical notation by writing:
  \[ c = 2*(a-3) + 5*b; \]

• However, many languages like C only have operators defined for the *built-in* types.

• C++ is an exception: it allows you to redefine most of its operators for *user-defined* types. e.g. you may redefine +, −, etc. for types Complex, Matrix, Array, String, etc.
Example: Additions of Vectors

```cpp
class Vector
{
    double _x, _y;
public:
    Vector(double x, double y) : _x(x), _y(y) {}  
    double x() const { return _x; }
    double y() const { return _y; }
};

• To add 2 vectors, traditionally we would do like this:

    Vector add (const Vector& a, const Vector& b)
    {
        return Vector( a.x() + b.x(), a.y() + b.y() );
    }

    Vector a(1, 3), b(-5, 7), c(22, 2), d;
    d = add(a, add(b, c));
```
Non-Member Operator Function

• It would be nicer if we could write the last expression
  
  \[ d = \text{add}(a, \text{add}(b, c)); \]

  as
  
  \[ d = a + b + c. \]

• We can achieve that in C++ by simply replacing the name of the function \text{add}() by \text{operator+}().

  ```cpp
  Vector operator+ (const Vector& a, const Vector& b)
  {
      return Vector( a.x() + b.x(), a.y() + b.y() );
  }
  ```

  Vector a(1, 3), b(-5, 7), c(22, 2), d;
  d = a + b + c;
Operator Syntax

- `operator+` is a formal function name that can be used like any other function name.
- Here we have used the “nickname”-syntax to call `operator+`. Technically, we could instead have used the “formal address” `operator+` as follows:
  ```
  d = operator+(operator+(a, b), c);
  ```
  (But nobody would really write code like this.)
- Operators in C++ are just like ordinary functions, except that they also have a nicer syntax for calling them similar to the usual mathematical notations.
- The operator `+` has a formal name, namely `operator+` (consisting of 2 keywords), and a “nickname” namely `+`. 
Operator Syntax

- The nickname can only be used when calling the function.
- The formal name can be used in any context, when declaring the function, defining it, calling it, or taking its address.
- There is nothing that you can do with operators that cannot be done with ordinary functions. In other words, operators are just syntactic sugar.
- Be careful when defining operators. There is nothing that inhibits you from defining $+$ to denote subtraction. There is nothing that inhibits you from defining $a = a + b$ and $a += b$ to have two different meanings. However, this would be extremely bad style – your code will become unreadable.

  Don't shock the user!
C++ Operators

• Almost all operators in C++ can be overloaded except:
  .  ::  ?:  sizeof

• The C++ parser is fixed. That means that you can only redefine existing operators, but you CANNOT define new operators.

• Nor can you change the following properties of an operator:
  – Arity: the number of arguments an operator takes.
    e.g. !x   x+y   a%b   s[j]
    (So you are not allowed to re-define the plus operator to take 3 arguments instead of 2.)
  – Associativity: e.g. a+b+c is always identical to (a+b)+c.
  – Precedence: which operator is done first?
    e.g. a+b*c is treated as a+(b*c).
C++ Operators

• All C++ operators already have predefined meaning for the built-in types. It is impossible to change this meaning; you can only overload the operator to have a meaning for your own (user-defined) classes (such as `Vector` in the example above).

• Therefore, every operator you define must have at least one argument of a user-defined class type.

• As a global function, `operator+` has two arguments. When it is called in an expression such as `a + b`, this is equivalent to writing `operator+(a, b)`.
Member Operator Function

- Member functions are called using the “dot syntax” by specifying an object of, for example, type `Vector`.
  - The expression `a + b` is equivalent to `a.operator+(b)`.
  - Thus, when we define `operator+` as a member function of `Vector`, it has only one argument – the first argument is `implicitly` the object on which the member function is invoked.

```cpp
class Vector {
    double _x, _y;

public:
    Vector(double x, double y) : _x(x), _y(y) {}
    double x() const { return _x; }
    double y() const { return _y; }
    Vector operator+ (const Vector& b) const
    { return Vector( _x + b._x, _y + b._y ); }
};
```
Member and Non-Member Operator Function

• Whenever the compiler sees an expression of the form \( a+b \), it converts this to the two possible representations:
  
  \[
  \begin{align*}
  \text{operator+}(a, b) \\
  a.\text{operator+}(b)
  \end{align*}
  \]

  and verifies whether one of those two operator functions are defined.

• Note: It is an error to define both.
Example: Member or Non-Member Function?

• Let's define a multiplication operator to multiply a vector with a scalar. This should all work:

```cpp
Vector a(1,0), b(2, 3);
Vector c = 2 * a; // c == (2, 0)
a = c + b * 3;    // a == (8, 9)
```

• Can we define the multiplication operator as a member function of Vector?

• Remember that the compiler converts the expression `a*b` to `a.operator*(b)`. So the expression `2*a` is converted to `2.operator*(a)`!
Example: Member or Non-Member Function?

- This doesn't work! 2 is an object of type \texttt{int}, and we cannot define a new member function for this type.
- So our only choice is to define the multiplication operator as a global non-member function:

\begin{verbatim}
Vector operator* (double s, const Vector& a)
{
    return Vector(s * a.x(), s * a.y());
}
\end{verbatim}
Example: Operator Function for Printing

- Very often you would like to provide a printing service for your user-defined classes, and the most natural way of doing that is to define the `<<` operator for your class.

```cpp
ostream& operator<<(ostream& os, const Vector& a)
{
    os << '}' << a.x() << ',' << a.y() << ';
    return os;
}
```

- `ostream` is the base class for all possible output streams.
- In particular, the standard output stream `cout` and the error output stream `cerr` are objects of classes derived from `ostream`. 
Example: Operator Function for Printing

- Why does the operator return an output stream?
- Because we like to write expressions such as:
  ```cpp
  Vector a(1, 0);
  cout << " a = " << a << "\n";
  ```
- The second line is equivalent to:
  ```cpp
  operator<<( operator<<( operator<<(cout, " a = "), a), "\n");
  ```
- This can only work if `operator<<` returns the output stream itself.
- Quiz: Could we have defined `operator<<` as a member function?
Operator: Member or Non-Member Functions?

- The operators: "=" (assignment), "[ ]" (indexing), "( )" (call) are required by C++ to be defined as class member functions.
- A member operator function has an implicit first argument of the class. => if the left operand of an operator must be an object of the class, it can be a member function.
- If the left operand of an operator must be an object of other classes, it must be a non-member function. e.g. `operator<<`
- To allow automatic conversion of types using the conversion constructor, for commutative operators like "+", "-", "*", it is usually preferred to be defined as non-member functions. e.g.

```java
String x("dot"), y("com"), z;
z = x + y;
z = x + "com";
z = "dog" + y;
```
How to Differentiate Prefix and Postfix Operators?

class Vector {
    // ...

public:
    Vector() : _x(0.0), _y(0.0) { }
    Vector(double x, double y) : _x(x), _y(y) { }
    Vector operator++() { ++_x; ++_y; return *this; }
    Vector operator++(int)
    {
        Vector temp(_x, _y); _x++; _y++; return temp;
    }
};

int main() {
    Vector a(1.2, 3.4), c, d;
    c = ++a; // a = (2.2, 4.4) and c = (2.2, 4.4)
    d = a++; // a = (3.2, 5.4) and d = (2.2, 4.4)
}
